Background

• Female sex workers (FSW) in South Africa have a disproportionately high burden of HIV, even in the context of the largest HIV epidemic in the world.
• Disclosure of HIV status is encouraged between couples; however, less is known about the patterns and determinants of disclosure between FSW and their male clients.
• This study aimed to quantify the proportion of HIV positive FSW who disclose their HIV status to paying clients and to characterize predictors of disclosure.

Methods

• Adult FSW were recruited using respondent driven sampling (RDS) in Port Elizabeth, South Africa from October 2014-March 2015.
• A total of 410 participants completed a structured survey instrument. Of these, 213 knew they were living with HIV and were included in the analysis.
• Stata version 14.1 and logistic regression modeling were used to measure associations between disclosing HIV status to clients and individual/client characteristics.

Results

Table 2. Multivariate adjusted associations of FSW HIV disclosure to clients with individual and client relationship characteristics

</tbody>
</table>

Conclusions

• These results suggest that FSW are more likely to disclose their HIV status to clients if they have more open communication patterns with clients, family and non-paying partners.
• Meeting clients in unfamiliar surroundings and a history of violence appear to be barriers to disclosure.
• Disclosure behavior was not associated with condom use with clients or ARV treatment, therefore more research is required to fully contextualize these findings, including research on male clients' perspectives and HIV status.
• These preliminary findings suggest that service delivery partners and government may be able to increase disclosure through a combination of providing a safer sex-work working environment and efforts to increase communication skills.
